

# MONSTOR: An **Inductive** Approach for Estimating and Maximizing Influence over **Unseen** Networks

Jihoon Ko

Kyuhan Lee

Kijung Shin

Noseong Park

# Social relationship can be represented as graph!

# Social relationship can be represented as graph!

# Information cascade in social relationship

# Information cascade in social relationship

# Influence Maximization

- Find a certain number of seed nodes to **maximize** the spread of information through a social network

- Two major issues
  - 1) **How to model** the information cascade
  - 2) **How to solve** the problem based on information cascade model

# How to model the information cascade

- Independent Cascade (IC)

- When node  $v$  becomes active, it has a **single** chance of activating each currently inactive neighbor  $w$
- The activation attempt succeeds with some probability  $p_{vw}$

with probability 0.2

with probability  $(1 - 0.2)$

- Linear Threshold (LT)

- Each node  $v$  has threshold  $p_v$ , and it is activated by its neighbors when at least  $p_v$  fraction of its neighbors are active

# How to solve the problem based on IC model

- Greedy approach [KKT03]
  - Greedily choose nodes using Monte-Carlo simulations repeatedly
  - Guarantees the approximation ratio of  $\left(1 - \frac{1}{e}\right)$
  - $d$  (usually set to 10,000) simulations takes  $O(d|\mathcal{E}|)$  time!  
=> performance bottleneck 😞
- CELF [LKGFVG07], UBLF [ZZGZG13] still rely heavily on MC simulations!
  - CELF significantly reduced MC simulations using submodular property
  - UBLF derived upper bound of marginal gain for every node at initialization step

# How to solve the problem based on IC model

- Greedy approach [KKT03]
  - Greedily choose nodes using Monte-Carlo simulations repeatedly
  - Guarantees the approximation ratio of  $\left(1 - \frac{1}{e}\right)$
  - $d$  (usually set to 10,000) simulations takes  $O(d|\mathcal{E}|)$  time!  
=> performance bottleneck 😞
  - CELF [LKGFVG07], UBLF [ZZGZG13] still rely heavily on MC simulations!

Solution: Estimate results from repeated MC simulations in fast!

# Outline

- Preliminaries
- Proposed method: MONSTOR
- Experimental Results
- Summary

# Preliminaries

- **Activation Probability** from  $u$  to  $v$ 
  - The success probability that the node  $u$  activates its neighbor  $v$  when  $u$  is infected

- Bernoulli Trial (BT):

$$p_{uv} = \frac{|actions(u,*) \cap actions(v,*)|}{|actions(u,*)|}$$

- Jaccard Index (JI):

$$p_{uv} = \frac{|actions(u,*) \cap actions(*,v)|}{|actions(u,*) \cup actions(*,v)|}$$

- Linear Probability (LP):

$$p_{uv} = \frac{|actions(u,*) \cap actions(*,v)|}{|actions(*,v)|}$$

## Notation

$actions(x,*)$  : the set of actions done by node  $x$

$actions(*,x)$  : the set of actions whose object is node  $x$

# Preliminaries

- Activation probability matrix

- The adjacency matrix when weighting each directional edge  $(u, v)$  by  $p_{(u,v)}$

- Infection Probability for node  $v$  given a seed set  $S$

- The probability that  $v$  is infected under the IC model with  $S$
- Defined as  $\rho(v)$

- Infection probability vector

- $\pi := [\rho(v)] \in [0,1]^{|V|}$  be the vector of  $\rho(v)$
- $\pi_i$  be the infection probability vector during the first  $i$  steps

# Our problems

- Influence Estimation (IE)

- Given a seed set  $S$ ,
- Estimate its influence  $\sum_{v \in \mathcal{V}} \rho(v)$  (the expected number of infected nodes)

- Influence Maximization (IM)

- Given the number of seed nodes  $k$ ,
- Find the set  $S$  of  $k$  seed nodes
- to Maximize the influence  $\sum_{v \in \mathcal{V}} \rho(v)$

# Outline

- Preliminaries
- Proposed method: MONSTOR
- Experimental Results
- Summary

# Proposed method: MONSTOR

- Neural network-based method for estimating MC simulation results under IC model
- MONSTOR can estimate MC simulation results in social networks **unseen** during training
- Significantly speeds up existing IM methods by **replacing** simulations

# Overall Workflow

# Overall Workflow

- 1) Collect one or more social networks  $\{\mathcal{G}_1, \mathcal{G}_2, \dots\}$

|           | $ \mathcal{V} $ | $ \mathcal{E} $ | $\sum p_{(u,v)} /  \mathcal{E} $ in BT |        | $\sum p_{(u,v)} /  \mathcal{E} $ in JI |        | $\sum p_{(u,v)} /  \mathcal{E} $ in LP |        |
|-----------|-----------------|-----------------|----------------------------------------|--------|----------------------------------------|--------|----------------------------------------|--------|
|           |                 |                 | Train                                  | Test   | Train                                  | Test   | Train                                  | Test   |
| Extended  | 11,409          | 58,972          | 0.0797                                 | 0.0919 | 0.0335                                 | 0.0410 | 0.1614                                 | 0.1837 |
| WannaCry  | 35,627          | 169,419         | 0.0726                                 | 0.0947 | 0.0298                                 | 0.0449 | 0.1979                                 | 0.1630 |
| Celebrity | 15,184          | 56,638          | 0.0321                                 | 0.0279 | 0.0016                                 | 0.0016 | 0.2614                                 | 0.256  |

# Overall Workflow

2) From each  $\mathcal{G}_j$ , collect the tuples  $\{(\pi_i, \pi_{i-1}, \dots, \pi_{i-e}, \mathbf{P}_j) : i \geq e\}$ , after choosing a seed set  $S$  randomly

- $e > 1$  is a hyperparameter
- $\mathbf{P}_j \in \{\text{BT, JI, LP}\}$
- Repeat multiple times with different seed sets

## Notation

$\pi_i$  be the infection probability vector during the first  $i$  steps

# Overall Workflow

3) Train GCN-based model  $M$  with  $l$  layers, estimating  $\pi_i$  given

$\pi_{i-1}, \dots, \pi_{i-e}$

- Estimates **a single step** of the IC model

# Overall Workflow

## 4) Stack $s$ times the pre-trained model

- The stacked model estimates  $\pi_s$  from  $\pi_0$
- Estimates **end-to-end** simulations

5-1) For **IE** problem, compute  $\langle \mathbf{1}, \pi_s \rangle$

5-2) For **IM** problem, replace the MC simulation subroutine of existing IM algorithms with MONSTOR

# Detailed Design

- Final output of our model is determined to

$$M(\pi_{i-1}, \dots, \pi_{i-e}, \mathbf{P}; \boldsymbol{\theta}) := \min\{\pi_{i-1} + h^l, u_i\}$$

, where  $u_i := \pi_{i-1} + (\pi_{i-1} - \pi_{i-2})\mathbf{P}$  (theoretical upper bound)

# Detailed Design

- Training/Validation: online postings (and their cascade logs) during the first 50% of time (1,600 training / 400 validation tuples)
- Test: those during the remaining 50% of time (2000 testing tuples)

# Outline

- Preliminaries
- Proposed method: MONSTOR
- Experimental Results
- Summary

# Experiments

- Q1. Accuracy in Influence Maximization
- Q2. Accuracy in Influence Estimation
- Q3. Scalability
- Q4. Submodularity

# Competitors

- Simulation-based algorithms: Greedy with MC simulations
  - UBLF for BT, JI
  - CELF for LP
- Non-simulation-based algorithms
  - SSA / D-SSA [NTD16]
  - PMIA [CWW10] / IRIE [JHC12]
- **Our proposed approach**
  - For BT, JI: **U-MON** (UBLF with MONSTOR)
  - For LP: **C-MON** (CELF with MONSTOR)

# Experimental Settings

- For training: two out of three networks
- For testing: Choose each of the three networks
- **Inductive** setting: testing with the graph unseen during training
  - Ex) U/C-MON (E+W)

# Q1. Influence Maximization (IM)

- Question: How **accurate** are simulation-based IM algorithms equipped with MONSTOR, compared to competitors?
- Answer: Test with BT/JI - **U-MON** was most accurate in most cases

Test with BII

| PMIA             | 1830.0        | 2828.9        | 3243.2        | 5196.7        | 7807.6        | 8981.8        | 5508.5        | 5604.2        | 5630.2        |

## Q2. Influence Estimation (IE)

- The ground-truth influences of test seed sets and the estimated influences were highly correlated

| Model                         | Target graph          | BT                                                                                    | JI                                                                                    | LP                                                                                    |
|-------------------------------|-----------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| U-MON (E+W)<br>or C-MON (E+W) | Celebrity<br>(Unseen) |    |    |    |
| U-MON (E+C)<br>or C-MON (E+C) | WannaCry<br>(Unseen)  |   |   |   |
| U-MON (W+C)<br>or C-MON (W+C) | Extended<br>(Unseen)  |  |  |  |

## Q3. Scalability

- **Question:** How rapidly does the estimation time grow as the size of the input graph increase?
- **Answer:** The runtime per stacked GCN was **near-linear** in the number of edges in the input graph

| $ \mathcal{E} $       | $2^{20}$ | $2^{21}$ | $2^{22}$ | $2^{23}$ | $2^{24}$ | $2^{25}$ | $2^{26}$ |
|-----------------------|----------|----------|----------|----------|----------|----------|----------|
| Estimation time (sec) | 11.5     | 17.7     | 31.0     | 56.3     | 108.9    | 411.0    | 819.7    |

## Q4. Submodularity

- **Question:** Is MONSTOR submodular as the ground-truth influence function is?
- Using each pair  $S$  and  $T$  of the seed sets, we tested whether

$$f(S) + f(T) \geq f(S \cup T) + f(S \cap T)$$

is met or not

- **Answer:** Influence estimation by MONSTOR can be considered as **submodular** in practice

|             | Extended | WannaCry | Celebrity |
|-------------|----------|----------|-----------|
| C-MON (E+W) | 0.9993   | 0.9997   | 0.9938    |
| C-MON (E+C) | 0.9994   | 0.9997   | 0.9970    |
| C-MON (W+C) | 0.9992   | 0.9996   | 0.9945    |

The ratio of the cases where the submodularity holds (Tested with LP)

# Outline

- Preliminaries
- Proposed method: MONSTOR
- Experimental Results
- Summary

# Summary

we present **MONSTOR**, an inductive learning algorithm for estimating the influence of seed nodes under the IC model.

**Accurate** in IM/IE Tasks

Most accurate in

**17 / 27**

Cases

**Scalable & Submodular**

The code and datasets used in the paper are available at  
<https://github.com/jihoonko/asonam20-monstor/>

# MONSTOR: An **Inductive** Approach for Estimating and Maximizing Influence over **Unseen** Networks
